Conceptual groundwork:
Each statement is represented with a set. Though this might seem arbitrary during initial observation but upon closer inspection it can be understood as the representation of occurence or lack thereof of the action or claim presented in the original logical statement or claim within assumed set of premises pr within that presumed condition, one of which is our real world where the factuality of said statement can be obtained through experimentation or deduction.
The parallel between sets and logical statements is made in the following format:
True(statement)=highlighted(set)
The assignment of truth value is done with the following convention:

1. If the given statement turns out to be true, then the set is assumed to have an element and is highlighted.
2. If the statement turns out to be false, then set is assumed to not have an element and is not highlighted.
3. For the overlap of statements, which involves more than one set, the included set is only highlighted when both statements are true.
4. In order to obtain the full logical operations in set, the highlighted parts for all possible combinations of truth values are collected and overlaid.

point to be noted: For all A,B is true. A intersection B is highlighted, not all of A and B. For all A is true and B is false A^0 is highlighted .

Now the logical operatives can be represented by the following set notations:
And, Or, not->trivial
Implication(A->B) =~A^0
Double implication (A⇔B)=~A^0 intersect~B^0

It's too easy, i suspect it is because set is bound to rules of logic hence the rules manifesting themselves.
